- 1. Give the Θ for the following and justify your answer:
 - (a) $5n^2 + 4n + 3$

 $f(n) \in \Theta(n^2)$, since n^2 is dominant term.

(b) $2^n + n!$

 $f(n) \in \Theta(n!)$, since n! is dominant term.

(c) $n^2 + 2^n$

 $f(n) \in \Theta(2^n)$, since 2^n is dominant term.

(d) $\log(n) + n$

 $f(n) \in \Theta(n)$, since n is dominant term.

(e) log(n!)

$$\log(n!) = \log\left(\prod_{i=1}^{n} k_i\right) = \sum_{k=1}^{n} \log(k) \in \Theta(n \log n)$$

2. Give a closed form for the following, then give the Θ

(a)
$$a_0 = 5$$

 $a_n = 3a_{n-1}$

$$= 5 + 3(5) + 3(3(5)5) + 3(3(3(15)))$$

$$= \sum_{k=0}^{n} 3^k (5) = \frac{5(3^{n+1} - 1)}{2} \in \Theta(3^n)$$

(b)
$$a_4 = 2$$

 $a_n = a_{n-1} + \log_2(n)$
 $= 2 + (2 + \log_2(5)) + (2 + (2 + \log_2(6)))$
 $= \sum_{k=5}^{n} 2 + (2 + \log_2(k))$
 $= \sum_{k=5}^{n} 2 + \sum_{k=5}^{n} 2 + \log_2(k)$
 $= \sum_{k=5}^{n} 2 + \sum_{k=5}^{n} 2 + \sum_{k=5}^{n} \log_2(k)$
 $= 2\sum_{k=5}^{n} 2 + \sum_{k=5}^{n} \log_2(k)$
 $= 2\sum_{k=5}^{n} 2 + \sum_{k=5}^{n} \log_2(k)$
 $= 4(n-4) + \log_2\left(\prod_{i=5}^{n} k_i\right)$
 $= 4(n-4) + \log_2(n!) \in \Theta(n\log_2((n)))$

(c)
$$a_1 = 1$$

 $a_n = 2a_{n-2} + 1$
 $= 1 + (2(1) + 1) + (2(3) + 1) + (2(7) + 1)$
 $= \sum_{k=0}^{n} 2k + 1 \iff k\%2 = 1$ i.e., sum over odd indices
 $= \sum_{k=0}^{n} 1 + \sum_{i=1}^{n} 2k + 1$
 $= n + n(n+1)$
 $= 2n + n^2 \in \Theta(n^2)$

(d)
$$T(1) = 1$$

 $T(n) = 3T(n/2) + 1$

$$a = 3, b = 2, k = \log_2(n), f(n) = 1$$

$$\implies T(n) = 3^k + \sum_{i=0}^{k-1} 3^i (1)$$

$$= 3^k + \sum_{i=0}^{k-1} 3^i$$

$$= 3^k + \frac{3^k - 1}{2}$$

$$= 3^{\log_2(n)} + \frac{3^{\log_2(n)} - 1}{2} \in \Theta\left(n^{\log_2(n)}\right)$$

(e)
$$T(1) = 4$$

 $T(n) = T(n/3) + 4$

$$a = 1, b = 3, k = \log_3(n), f(n) = 4$$

$$\implies T(n) = (1)(4) + \sum_{i=0}^{k-1} (1)(4)$$

$$= 4 + \sum_{i=0}^{k-1} 4$$

$$= 4 + 4(k-1)$$

$$= 4 \log_3(n) \in \Theta(\log_3(n))$$

3. (Extra Credit):

$$T(0) = 1$$

$$T(n) = 3T(n-2) + 4(n-2) + 2$$

$$a = 3, b = 2, k = \log_2(n), f(n) = 4(n-2) + 2$$

$$\implies T(n) = 3^k + \sum_{i=0}^{k-1} 3^i \frac{4n}{2^i} - 6$$

$$= 3^k + 4n \sum_{i=0}^{k-1} \left(\frac{3}{2}\right)^i - \sum_{i=0}^{k-1} 6$$

$$= 3^k + \frac{4n\left(\frac{3}{2}^k\right) - 1}{\frac{3}{2} - 1} - 6k - 6$$

$$= 3^{\log_2(n)} + \frac{4n\left(\frac{3}{2}^{\log_2(n)}\right) - 1}{\frac{3}{2} - 1} - 6\log_2(n) - 6$$

$$\in \Theta\left(n^{\log_2(n)}\right)$$

- 4. Prove **theorem 2:** $x^k \in \mathbf{O}(x^{k+c})$
- 5. Prove **theorem 3:** $x^k + c \cdot x^{k-r} \in \mathbf{O}(x^k)$
- 6. Prove **theorem 5:** if $f(n) \in \mathbf{O}(g(n))$ and $g(n) \in \mathbf{O}(h(n))$, then $f(n) \in \mathbf{O}(h(n))$

7. Give the $\boldsymbol{\Theta}$ running time for the following selection sort algorithm

```
def selSort(1):
    for i in range(len(1)):
        min = 1[i]
        minI = i
        for j in range(i,len(1)):
            if 1[j] < min:
                  minI = j
                  min = 1[j]
                  #end if
            # end for
            (1[i], min) = (min, 1[i])
            # end for</pre>
```

8. Give the recurrence relation for badSort. Remember 1[a:b] copies the elements from 1[a] to 1[b], so even though it's an expression 1[a:b] runs in n-2 time.

```
def badSort(1): n = len(1)

if n == 1:
    return l

first = badSort(1[0:n-2])
  middle = badSort(1[1:n-1])
  end = badSort(1[2:n])

return [first[0]] + middle + [end[n-1]]
```

9. The following algorithm is the merge sort we way in class

```
def merge(low, high):
                                         def mergeSort(lst):
    i = 0
                                              n = len(lst)
    j = 0
                                              n2 = int(n/2)
    merged = []
    while i < len(low) and j < len(high):
                                             # base case:
        if low[i] < high[j]:</pre>
                                             if n <= 1:
            merged += [low[i]]
                                                  return 1st
            i += 1
                                              # recursive case:
        else:
                                              low = mergeSort(lst[0:n2])
            merged += [high[j]]
            j += 1
                                              high = mergeSort(lst[n2:n])
                                              lst = merge(low,high)
    return merged + low[i:] + high[j:]
                                              return 1st
```

- (a) Give the Θ running time for merge. hint: what is the input size for merge?
- (b) Use (a) to give a recurrence relation for the running time of mergeSort.
- (c) Solve the recurrence to get a Θ running time for mergesort.
